Statistics for Business, Part IV

Example: Detecting Sex Discrimination

Imagine you are a trial lawyer and you want to file a suit against a company for salary discrimination... you gather the following data...

	Gender	Salary
1	Male	32.0
2	Female	39.1
3	Female	33.2
4	Female	30.6
5	Male	29.0
...	...	...
208	Female	30.0

Detecting Sex Discrimination

You want to relate salary(Y) to gender(X)... how can we do that?

Gender is an example of a categorical variable. The variable gender separates our data into 2 groups or categories. The question we want to answer is: *"how is your salary related to which group you belong to..."*

Could we think about additional examples of categories potentially associated with salary?

- MBA education vs. not
- legal vs. illegal immigrant
- quarterback vs wide receiver

Detecting Sex Discrimination

We can use regression to answer these question but we need to recode the categorical variable into a dummy variable

	Gender	Salary	Sex
1	Male	32.00	1
2	Female	39.10	0
3	Female	33.20	0
4	Female	30.60	0
5	Male	29.00	1
...	...	...	
208	Female	30.00	0

Note: In Excel you can create the dummy variable using the formula:

=IF(Gender="Male",1,0)

Detecting Sex Discrimination

Now you can present the following model in court:

$$Salary_i = \beta_0 + \beta_1 Sex_i + \epsilon_i$$

How do you interpret β_1?

$$\begin{aligned} E[Salary|Sex = 0] &= \beta_0 \\ E[Salary|Sex = 1] &= \beta_0 + \beta_1 \end{aligned}$$

β_1 is the male/female difference

Detecting Sex Discrimination

$$Salary_i = \beta_0 + \beta_1 Sex_i + \epsilon_i$$

Regression Statistics

Gender	8.295513	1.564493	5.3024	2.9E-07	5.211041089	11.3799841

$\hat{\beta}_1 = b_1 = 8.29...$ on average, a male makes approximately \$8,300 more than a female in this firm.

How should the plaintiff's lawyer use the confidence interval in his presentation?

Detecting Sex Discrimination

How can the defense attorney try to counteract the plaintiff's argument?

Perhaps, the observed difference in salaries is related to other variables in the background and NOT to policy discrimination...

Obviously, there are many other factors which we can legitimately use in determining salaries:

- education
- job productivity
- experience

How can we use regression to incorporate additional information?

Detecting Sex Discrimination

Let's add a measure of experience...

$$Salary_i = \beta_0 + \beta_1 Sex_i + \beta_2 Exp_i + \epsilon_i$$

What does that mean?

$$\begin{aligned} E[Salary|Sex = 0, Exp] &= \beta_0 + \beta_2 Exp \\ E[Salary|Sex = 1, Exp] &= (\beta_0 + \beta_1) + \beta_2 Exp \end{aligned}$$

Detecting Sex Discrimination

The data gives us the "year hired" as a measure of experience...

	Exp	Gender	Salary	Sex
1	3	Male	32.00	1
2	14	Female	39.10	0
3	12	Female	33.20	0
4	8	Female	30.60	0
5	3	Male	29.00	1
...	...	...		
208	33	Female	30.00	0

Detecting Sex Discrimination

$$Salary_i = \beta_0 + \beta_1 Sex_i + \beta_2 Exp + \epsilon_i$$

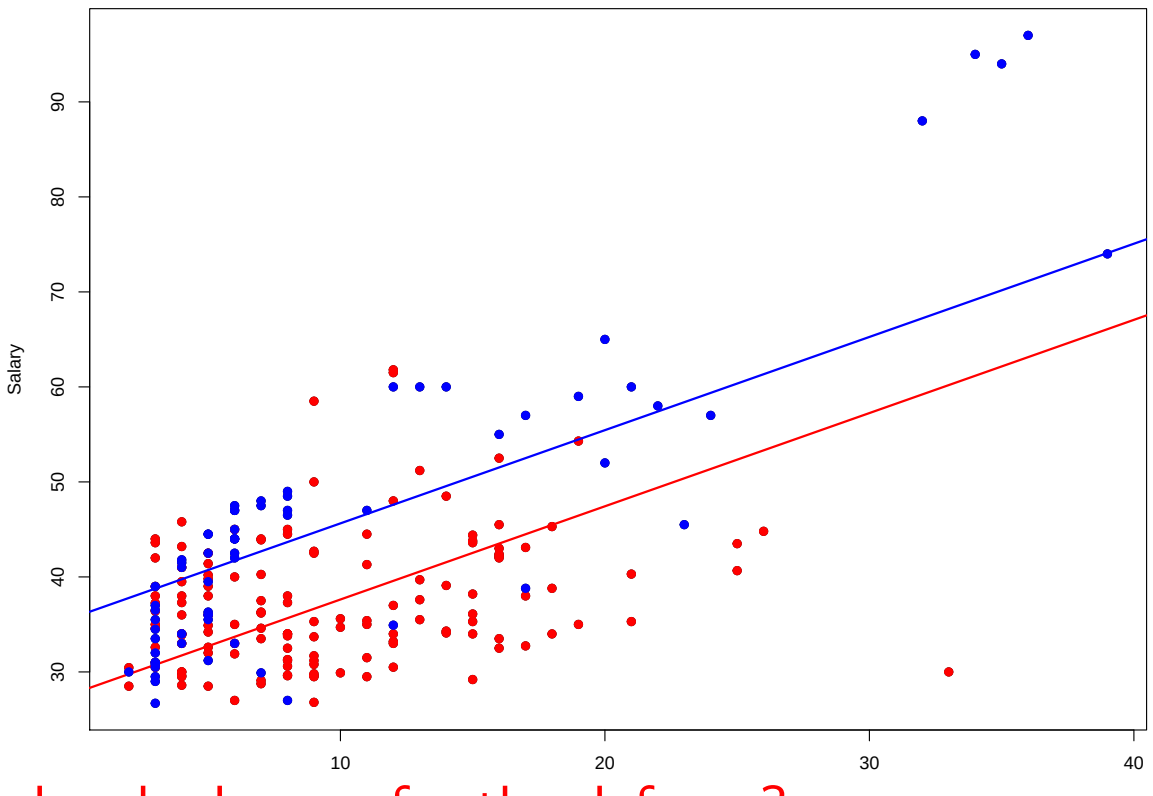
$$Salary_i = 27 + 8 Sex_i + 0.98 Exp_i + \epsilon_i$$

Is this good or bad news for the defense?

Detecting Sex Discrimination

$$Salary_i = \begin{cases} 27 + 0.98 Exp_i + \epsilon_i & \text{females} \\ 35 + 0.98 Exp_i + \epsilon_i & \text{males} \end{cases}$$



Is this good or bad news for the defense?

More than Two Categories

We can use dummy variables in situations in which there are more than two categories. Dummy variables are needed for each category except one, designated as the "base" category.

Why? *Remember that the numerical value of each category has no quantitative meaning!*

Example: House Prices

We want to evaluate the difference in house prices in a couple of different neighborhoods.

	Nbhd	SqFt	Price
1	2	1.79	114.3
2	2	2.03	114.2
3	2	1.74	114.8
4	2	1.98	94.7
5	2	2.13	119.8
6	1	1.78	114.6
7	3	1.83	151.6
8	3	2.16	150.7
...	...	...	...

Example: House Prices

Let's create the dummy variables $dn1$, $dn2$ and $dn3$...

	Nbhd	SqFt	Price	dn1	dn2	dn3
1	2	1.79	114.3	0	1	0
2	2	2.03	114.2	0	1	0
3	2	1.74	114.8	0	1	0
4	2	1.98	94.7	0	1	0
5	2	2.13	119.8	0	1	0
6	1	1.78	114.6	1	0	0
7	3	1.83	151.6	0	0	1
8	3	2.16	150.7	0	0	1
...	...	...				

Example: House Prices

$$Price_i = \beta_0 + \beta_1 dn1_i + \beta_2 dn2_i + \beta_3 Size_i + \epsilon_i$$

$$\begin{aligned}
E[Price|dn1 = 1, Size] &= \beta_0 + \beta_1 + \beta_3 Size \quad \text{(Nbhd 1)} \\
E[Price|dn2 = 1, Size] &= \beta_0 + \beta_2 + \beta_3 Size \quad \text{(Nbhd 2)} \\
E[Price|dn1 = 0, dn2 = 0, Size] &= \beta_0 + \beta_3 Size \quad \text{(Nbhd 3)}
\end{aligned}$$

Example: House Prices

$$Price = \beta_0 + \beta_1 dn1 + \beta_2 dn2 + \beta_3 Size + \epsilon$$

Example: House Prices

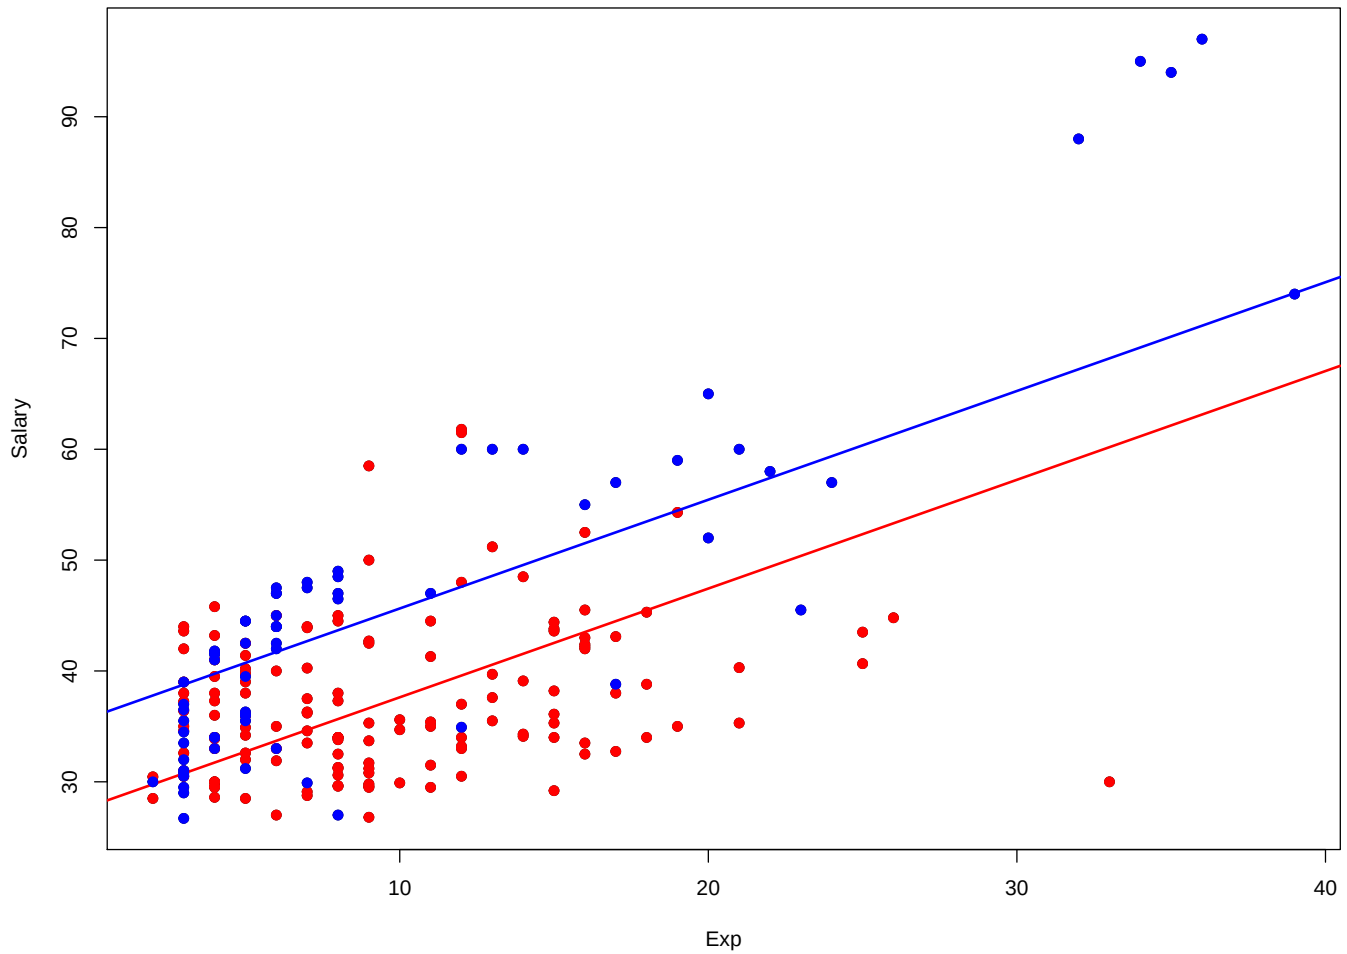
Back to the Sex Discrimination Case



Does it look like the effect of experience on salary is the same for males and females?

Back to the Sex Discrimination Case

Could we try to expand our analysis by allowing a different slope for each group?

Yes... Consider the following model:

$$Salary_i = \beta_0 + \beta_1 Exp_i + \beta_2 Sex_i + \beta_3 Exp_i \times Sex_i + \epsilon_i$$

For Females:

$$Salary_i = \beta_0 + \beta_1 Exp_i + \epsilon_i$$

For Males:

$$Salary_i = (\beta_0 + \beta_2) + (\beta_1 + \beta_3) Exp_i + \epsilon_i$$

Sex Discrimination Case

How does the data look like?

	Exp	Gender	Salary	Sex	Exp*Sex
1	3	Male	32.00	1	3
2	14	Female	39.10	0	0
3	12	Female	33.20	0	0
4	8	Female	30.60	0	0
5	3	Male	29.00	1	3
...	...	...			
208	33	Female	30.00	0	0

Sex Discrimination Case

$$Salary = \beta_0 + \beta_1 Sex + \beta_2 Exp + \beta_3 Exp * Sex + \epsilon$$

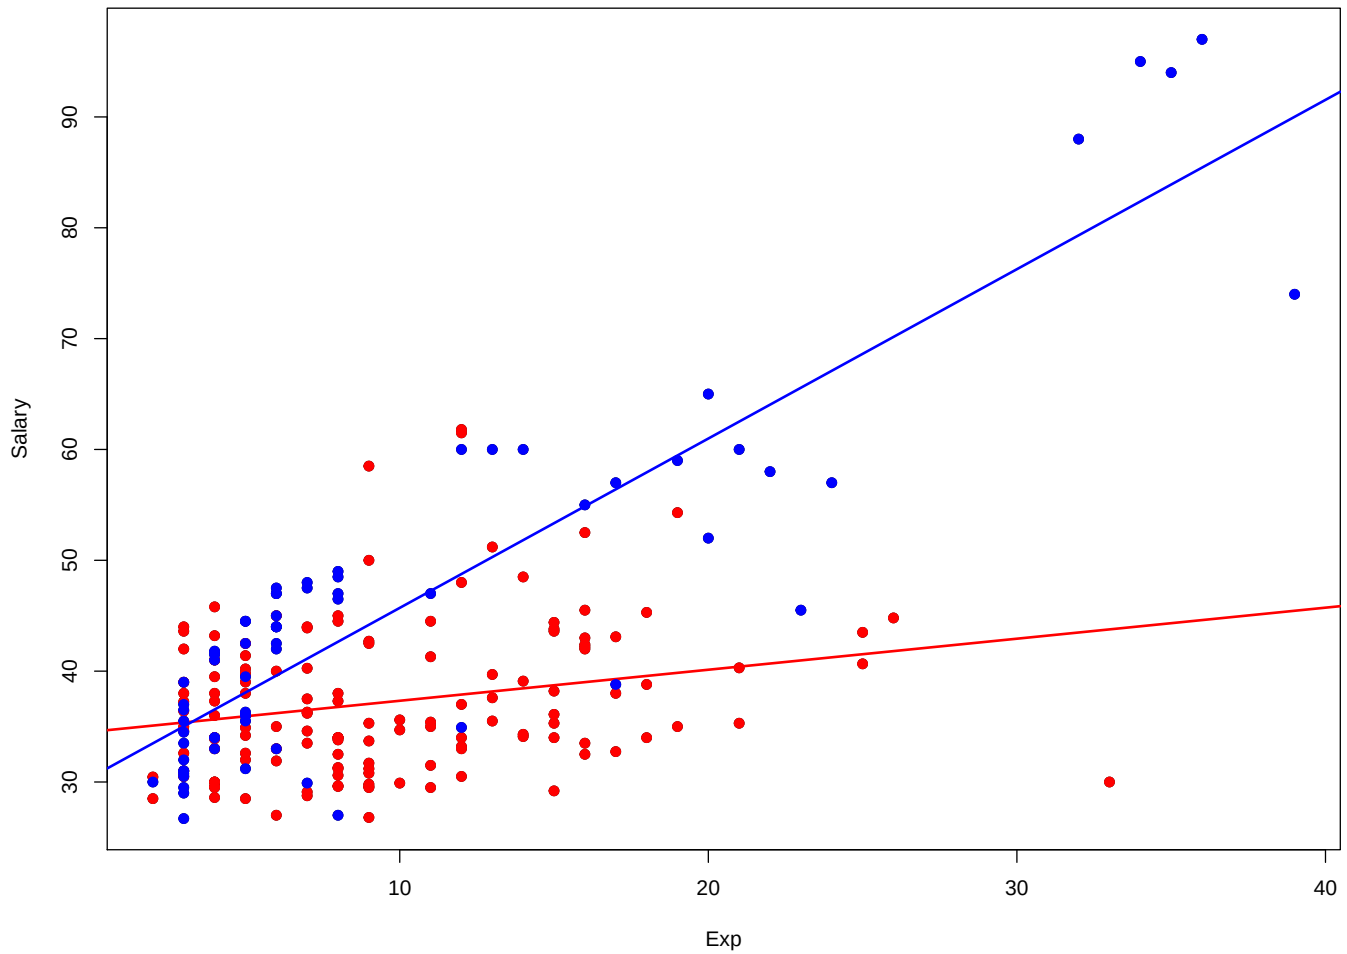
$$Salary = 34 - 4Sex + 0.28Exp + 1.24Exp * Sex + \epsilon$$

Sex Discrimination Case



Is this good or bad news for the plaintiff?

Variable Interaction

So, the effect of experience on salary is different for males and females... in general, when the effect of the variable X_1 onto Y depends on another variable X_2 we say that X_1 and X_2 interact with each other.

We can extend this notion by the inclusion of multiplicative effects through interaction terms.

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 (X_1 X_2) + \varepsilon$$

$$\frac{\partial E[Y|X_1, X_2]}{\partial X_1} = \beta_1 + \beta_3 X_2$$

Example: College GPA and Age

Consider the connection between college and MBA grades:

A model to predict MBA GPA from college GPA could be

$$GPA^{MBA} = \beta_0 + \beta_1 GPA^{Bach} + \varepsilon$$

	Estimate	Std.Error	t value	$Pr(>\|t\|)$
BachGPA	0.26269	0.09244	2.842	0.00607 **

For every 1 point increase in college GPA, your expected MBA GPA increases by about .26 points.

College GPA and Age

However, this model assumes that the marginal effect of College GPA is the same for any age.

It seems that how you did in college should have less effect on your MBA GPA as you get older (further from college).

We can account for this intuition with an interaction term:

$$GPA^{MBA} = \beta_0 + \beta_1 GPA^{Bach} + \beta_2 (Age \times GPA^{Bach}) + \varepsilon$$

Now, the college effect is $\frac{\partial E[GPA^{MBA} | GPA^{Bach} \ Age]}{\partial GPA^{Bach}} = \beta_1 + \beta_2 Age$.

Depends on Age!

College GPA and Age

$$GPA^{MBA} = \beta_0 + \beta_1 GPA^{Bach} + \beta_2 (Age \times GPA^{Bach}) + \varepsilon$$

Here, we have the interaction term but do not the main effect of age. . . what are we assuming?

	Estimate	Std.Error	t value	$Pr(>\|t\|)$
BachGPA	0.455750	0.103026	4.424	4.07e-05 ***
BachGPA:Age	-0.009377	0.002786	-3.366	0.00132 **

College GPA and Age

Without the interaction term

- Marginal effect of College GPA is $b_1 = 0.26$.

With the interaction term:

- Marginal effect is $b_1 + b_2 Age = 0.46 - 0.0094 Age$.

Age	Marginal Effect
25	0.22
30	0.17
35	0.13
40	0.08
